Abstract—Interesting signals are often contaminated by heavy-tailed noise that has more outliers than Gaussian noise. Under the introduction of probability model for heavy-tailed noises, a robust wavelet threshold based on the minimax description length principle is derived in the \( \varepsilon \)-contaminated normal family for maximizing the entropy. The performance and their measurement criterion for the robust wavelet threshold are studied in this paper. By the proposed performance measurement criterion, several kinds of noisy signals are processed with the wavelet thresholding techniques. Compared with classical threshold based on Gaussian assumption, the robust threshold can eliminate the heavy-tailed noise better, even if the precise value of \( \varepsilon \) is unknown, which shows its robustness. The further experiment shows that soft threshold is more suitable than hard threshold for robust wavelet threshold technique. Finally, the robust threshold technique is applied to denoise the practically measured gas sensor dynamic signals. Results show its good performances.

Index Terms—heavy-tailed noise, robust wavelet threshold, soft threshold, hard threshold, signal detection

I. INTRODUCTION

Wavelet analysis has recently played a more and more important role in signal processing applications [1-3]. Many simple nonlinear thresholding filters based on wavelets have acted effectively for denoising [4-6]. Based on singularity of signals, Mallat has suppressed noise effectively in wavelet transform domain by preserving only the local maxima of the transform coefficients [7]. The noise suppression is achieved by thresholding the wavelet transform of the contaminated signal. And Donoho has derived a threshold by a minimax approach based on Gaussian noise model [8]. This thresholding technique has been applied to many areas to reduce the normally distributed white noises, such as ECG signals and image signals [4,9].

However, in practical case, the contaminated signals such as radar, sonar echo signals and most other signals contain many noises with large magnitudes, which do not subject to Gaussian distribution, but a heavy-tailed noise model [10]. The noise is assumed to be independent and identically distributed (i.i.d) with a density which is a member of an \( \varepsilon \)-contamination class for which the nominal distribution has heavier than exponential tails [11]. For heavy-tailed noise has more outliers than Gaussian noise, many methods based on Gaussian noise model cannot gain perfect effectiveness for heavy-tailed noise [12]. Thus a robust wavelet threshold method based on the minimax description length principle is derived, which determines the least favorable distribution in the \( \varepsilon \)-contaminated normal family as the member that maximizes the entropy [12]. This robust wavelet threshold technique is in detail studied including its performances, and the measurements of performances, and the application to denoise the practically measured gas sensor signals.

This paper is constructed as follows. Firstly the probability model for heavy-tailed noises and the robust wavelet threshold technique are introduced and analyzed. Then based on an appropriate effectiveness measure for removing heavy-tailed noise, the classical threshold method and the robust wavelet threshold method are compared by Monte Carlo simulation. Moreover, the soft threshold and hard threshold for robust wavelet threshold technique are also analyzed and compared. An application in gas sensor signal denoising shows the prospect of the robust wavelet threshold technique. Finally, some conclusions are given as well as the hints for future work.

II. MODEL FOR HEAVY-TAILED NOISES

Generally, the observed signals are illustrated through the additive noise model, which is given by

\[
x(t) = s(t) + n(t)
\]

where \( s(t) \) is an unknown deterministic signal, \( n(t) \) is the zero-mean noise process, and \( x(t) \) is the observed signal.
The aim of denoising is to recover the signal $s(t)$ from the noisy signal $x(t)$. In order to reach this purpose, the noise process is usually supposed to subject to Gaussian distribution. Under this assumption, many methods have been proposed.

In most applications, the data are assumed to be conditionally normal, and the likelihood is therefore Gaussian. Here for heavy-tailed noises, the noise probabilistic distribution model is constructed by Huber [13]. Assuming that the noise distribution $f$ is a scaled version of an unknown member of the family of $\varepsilon$-contaminated normal distribution,

$$P_\varepsilon = \{(1-\varepsilon)\Phi + \varepsilon G : G \in F\}$$  \hspace{1cm} (2)

where $\Phi$ denotes the standard normal distribution, $F$ denotes the set of all suitably smooth distribution functions, and $\varepsilon \in (0,1)$ is the known fraction of contamination.

Krim and Shick [12] also followed this assumption and obtained same model by solving a minimax problem. They denoted that the signal estimation problem can be cast as one of location parameter estimation and the estimators can be assumed to be in the set of all integrable mappings from $\mathfrak{g}$ to $\mathfrak{g}$. By solving a minimax problems where the entropy is maximized over all distributions in $P_\varepsilon$, the least favorable noise distribution is found and the minimax description length(MDL) criterion for that distribution is evaluated. And the description length is minimized over all estimators in the set of all integrable mappings from $\mathfrak{g}$ to $\mathfrak{g}$.

The least favorable noise distribution in $P_\varepsilon$ which maximizes the entropy, is precisely the same as that found by Huber to maximize the asymptotic variance: it is Gaussian in the center and Laplacian in the tails, and switches from one to the other at a point whose value depends on the fraction of contamination $\varepsilon$. Larger fractions corresponding to smaller switching points and vice versa. This distribution $f_\varepsilon \in P_\varepsilon$ that minimizes the negentropy is obtained and defined as

$$f_\varepsilon(\varepsilon) = \begin{cases} (1-\varepsilon)\phi_\varepsilon(a) e^{\frac{1}{2}\sigma^2 (b-a)}, & c \leq -a \\ (1-\varepsilon)\phi_\varepsilon(c), & -a < c < a \\ (1-\varepsilon)\phi_\varepsilon(a) e^{\frac{1}{2}\sigma^2 (a-c)}, & c \geq a \end{cases} \hspace{1cm} (3)$$

where $\phi_\varepsilon$ is the normal density function with mean zero and variance $\sigma^2$, and $a$ is related to $\varepsilon$.

Let $\Phi_\sigma$ be the normal distribution function with mean zero. According to the symmetry of $f_\varepsilon$, the relationship between $a$ and $\varepsilon$ is given by

$$\frac{2\phi_\varepsilon(a)}{a/\sigma^2 - \Phi_\sigma(-a)} = \frac{\varepsilon}{1-\varepsilon}$$ \hspace{1cm} (4)

The above propositions and their proofs can be found in [12].

According to (4), let $\sigma = 1$, the relationship between $a$ and $\varepsilon$ is shown in Fig. 1. In the interval $(0, 0.1)$, $a$ decreases sharply as $\varepsilon$ increases, but in the interval $(0.1, 1)$ the variation curve is flat. When $\varepsilon \to 1$ and $a \to 0$, the noise distribution approaches Laplacian, but when $\varepsilon \to 0$ and $a \to \infty$, the noise distribution approaches purely Gaussian.

### III. ROBUST WAVELET THRESHOLD TECHNIQUE

#### A. The Basic Principle of Wavelet Transform

Wavelet transforms have become well known as useful tools for various signal processing applications [14]. Given a time-varying signal $x(t)$, wavelet transforms consist of computing coefficients that are inner products of the signal and a family of “wavelets”. In a continuous wavelet transform, the wavelet corresponding to scale $a$ and time location $b$ is

$$\psi_{a,b}(t) = \frac{1}{\sqrt{|a|}} \psi(t - b/a)$$ \hspace{1cm} (5)

where $\psi(t)$ is the wavelet “prototype”, which can be thought of a band-pass function. The factor $|a|^{-1/2}$ is used to ensure energy preservation.

The continuous wavelet transform (CWT) was originally introduced by Goupillaud, Grossmann, and Morlet [15]. Time $t$ and the scale-time parameters vary continuously:

$$CWT[x(t); a, b] = \int x(t) \psi_{a,b}^*(t) dt$$ \hspace{1cm} (6)

( the asterisk stands for complex conjugate).

Wavelet series coefficients are sampled CWT coefficients. There are various ways of discretizing time-scale parameters $(b, a)$, each one yields a different type of wavelet transform. The time-scale parameters $(b, a)$ are usually sampled on a so-called “dyadic” grid in the time-scale plane $(b, a)$, where the dilation or scale is supposed to $a = 2^j$, the translation $b$ is supposed to $b = k2^j$, $j \in \mathbb{Z}$, $k \in \mathbb{Z}$ . Hence the scale and translation are denoted through $j$ and $k$. And the discrete wavelet transform (DWT) is defined as

© 2011 ACADEMY PUBLISHER
\( C_{j,k} = \int x(t)\psi^*_j(t) dt \). (7)

The wavelet transform is used to transform the noisy signal into wavelet domain by decomposing the noisy signal into different levels of details coefficient. And the signal could be reconstructed through the inverse wavelet transform

\[ x(t) = \sum_{j=2}^{N} \sum_{k=-2}^{2} C_{j,k} \tilde{\psi}_{j,k}(t). \]  

If \( \psi(t) = \tilde{\psi}(t) \), the wavelet basis is called orthogonal basis. Wavelet series have been popularized under the form of signal decomposition onto “orthogonal wavelets” by Meyer, Mallat, Daubechies, and other authors [16–17].

\( C_{j,k} \) is also called the wavelet coefficient, \( j, k \) are usually integers which show the scale and translation parameters. For signal denoising, we do not concern the \( j, k \) parameters, but the amplitude. To simplify, let the set of wavelet coefficients obtained from the observed signal be denoted by \( C^N = \{ C_1^N, C_2^N, \ldots, C_N^N \} \). Considering the orthogonal wavelets, equation (8) is changed to

\[ x(t) = \sum_{i=1}^{N} C_i^s \psi_i(t). \]  

And the signal and noise can be expressed with an orthonormal basis:

\[ s(t) = \sum_{i} C_i^s \psi_i(t); \]  
\[ n(t) = \sum_{i} C_i^n \psi_i(t); \]  

As wavelet transform is linear, \( x(t) \) can be given by

\[ C_i^s = C_i^n + C_i^s. \]  

Let exactly \( K \) of these coefficients contain signal information, while the remainder only contains noise. If necessary, these coefficients are reindexed as

\[ C_i^s = \begin{cases} C_i^n + C_i^s, & i = 1, 2, \ldots, K, \\ C_i^n, & \text{otherwise} \end{cases}. \]  

By assumption, the set of noise coefficients \( \{ C_i^n \} \) is a sample of independent and identically distributed random variates drawn from Huber’s distribution \( f_H \).

From the above equations, if \( C_i^n = 0 \) for a given \( i \), it implies that the corresponding observation coefficients \( C_i^s \) represent “pure noise”. The wavelet denoising determines which wavelet coefficients represent signal primarily and which represent noise mainly.

B. Wavelet Threshold Denoising

Wavelet threshold denoising is based on the idea that the energy of the signal to be defined concentrates on some wavelet coefficients, while the energy of noise spreads throughout all wavelet coefficients. Similarity between the basic wavelet and the signal to be defined plays a very important role, making it possible for the signal to concentrate on fewer coefficients. Wavelet threshold denoising is a very efficient method, the purpose of which is to remove the noises [18].

Generally, the wavelet threshold denoising procedure has the following steps [8]:

1. Transform signal to the time-scale plane by means of a wavelet transform. It is possible to acquire the results of the wavelet coefficients on different scales.

2. Assess the threshold and in accordance with the established rules, shrink the wavelet coefficients.

3. Use the shrunken coefficients to carry out the inverse wavelet transform. The series recovered is the estimation of the determined signal.

The second step has a large impact upon the effectiveness of the procedure.

Thresholding is one of the important steps to remove noise. Thresholding function in this study covers hard and soft thresholding. Thresholding function is the wavelet shrinkage function which determines how the threshold is applied to wavelet coefficients. The definition of soft and hard threshold is given by [8].

The soft thresholding function is defined as

\[ T^\text{soft}(C, \theta) = \begin{cases} \text{sgn}(C)\max(|C| - \theta, 0), & |C| > \theta, \\ 0, & |C| \leq \theta \end{cases}. \]  

where \( C \) and \( \theta \) are wavelet coefficient and threshold. And the \( \text{sgn}(x) \) is the symbol function:

\[ \text{sgn}(x) = \begin{cases} 1, & x > 0, \\ -1, & x < 0 \end{cases}. \]  

It is called think or kill which is an extension of hard thresholding, first setting the elements whose absolute values are lower than the threshold to zero, and then shrinking the other coefficients.

The hard thresholding function used by Donoho is:

\[ T^\text{hard}(C, \theta) = \begin{cases} |C|, & |C| > \theta, \\ 0, & |C| \leq \theta \end{cases}. \]  

where \( C \) and \( \theta \) are wavelet coefficient and threshold.

It is called keep or kill, keep the elements whose absolute value is greater than the threshold to zero, and then shrinking the other coefficients.

C. Robust Wavelet Threshold

No matter hard thresholding or soft thresholding, the determination of the threshold is most critical. According to Donoho, the universal threshold rule should be applied in the second step. The universal threshold is defined as follows:

\[ \theta = \sigma \sqrt{2 \ln N}. \]  

Where \( \sigma \) refers to the standard deviation of the noise and if it is unknown, a robust median estimator is used from the finest scale wavelet coefficients: \( \sigma = \text{MAD}/0.6745 \), where MAD refers to the median absolute value of the
finest scale wavelet coefficients, whereas $N$ refers to the number of data samples in the measured signal. [18]

Equation (17) has been widely used as the threshold, which is quite classical. However, for heavy-tailed noises, according to $f_i$, the robust threshold technique is obtained as

1) When $\log N > a^2 / 2\sigma^2$, the coefficients $|C_i|$ will be truncated if

$$|C_i| < a + \frac{\sigma^2}{a} \log N.$$  \hspace{1cm} (18)

2) When $\log N \leq a^2 / 2\sigma^2$, the coefficients $|C_i|$ will be truncated if

$$|C_i| < \sigma \sqrt{2 \log N}.$$  \hspace{1cm} (19)

where $N$ denotes the length of coefficients at a given level.

The robust wavelet threshold adopts data description length as the criterion of choice for quantifying the tradeoff between noise removing and signal retaining. It can resolve the tradeoff between model complexity and goodness-of-fit well.

IV. SIMULATION RESULTS AND ANALYSIS

For comparison, the threshold defined by (17) is called as the classical threshold. Hence in the simulations, the classical threshold and the robust threshold are compared firstly. And then the sensitivity of robust threshold to $\varepsilon$ is discussed. By comparing the results of soft threshold and hard threshold, the better one for robust wavelet threshold technique is determined. Finally, the real gas sensor’s signal is denoised with the method.

A. Signal Denoising

In simulation experiments, both the sine wave signal and square wave signal are chosen as the original signals with length 1024. The additive noise is independent identically distributed and obeys $P$ with $\varepsilon = 0.1$. Suppose that $\Phi \sim N(0,1), A \sim N(0, \sigma^2)$ and the heavy-tailed noise obeys $G = A^3$ [17]. Let $\sigma = 1.6$ and SNR=8.5 dB. The soft thresholding is adopted for the experiment. The db4 wavelet is chosen for decomposition in MATLAB. The decomposition layer is set 5.

Fig. 2 shows the simulated sine wave signal and the noisy signal, where $S(n)$ and $X(n)$ are the original signal and contaminated signal respectively. Fig. 3 shows the detected sine wave signal with classical threshold and robust threshold, where $S_1(n)$ and $S_2(n)$ are the detected signal with classical threshold and robust threshold respectively. According to Fig. 2, compared with Gaussian noise, the heavy-tailed noise has more outliers. From Fig. 3 it can be seen that the classical threshold cannot suppress outliers in heavy-tailed noise effectively, while the robust threshold is efficient to decrease the heavy-tailed noise.

Fig. 4 shows the simulated square wave signal and the noisy signal, where $S(n)$ and $X(n)$ are the original signal and contaminated signal respectively. And Fig. 5 shows the detected square wave signal with classical threshold and robust threshold, where $S_1(n)$ and $S_2(n)$ are the detected signal with classical threshold and robust threshold respectively. It gives the same result as Fig. 2 and 3. And it can be seen that the robust wavelet threshold is robust both for narrow band signal and broad band signal.

B. Sensitivity to $\varepsilon$

$\varepsilon$ is the fraction of contamination from the heavy-tailed noise, it shows the noise distribution probability. According to (4), given $\varepsilon$, the parameter $a$ can be obtained and the noise distribution probability is set. Different values are set to $\varepsilon$ and the sensitivity of proposed threshold to $\varepsilon$ is discussed.

Assuming $\varepsilon = 0.1$, $\varepsilon = 0.01$, $\varepsilon = 0.99$, correspondingly $a$ is obtained as $a=1.14, a=1.95, a=0.008$ respectively. Fig. 6 shows the detection results with robust threshold under different estimated values of $\varepsilon$, where $S_2(n), S_1(n)$ and $S_4(n)$ correspond to the exact estimation of $\varepsilon=0.1, \varepsilon=0.01$ and $\varepsilon=0.99$ respectively. Compared with $S_1(n)$, the robust threshold can suppress outliers more effectively than the classical threshold. Although $S_2(n)$ retains outliers near $n=930$, it is still better than $S_1(n)$.
Hence it can be seen that the mixture parameter $\varepsilon$ plays little influence on the robust threshold, which shows its robustness.

$$SNR_{enh} = SNR_2 - SNR_1$$ (21)

where $SNR_1$ and $SNR_2$ are the SNR before and after denoising, with dB as the unit. The SNR is defined as

$$SNR = 10\log_{10} \left( \frac{\sum_i (S(i))^2}{\sum_i (N(i) - \mu_N)^2} \right)$$ (22)

where $S(i), N(i)$ and $\mu_N$ are signal series, noise series and noise mean value respectively [20].

$SNR_{enh}$ denote the average level of the noises in revised signals. Comparing to Gaussian noise, the heavy-tailed noise has more outliers. To denote the ability to suppress the outliers, the maximum error (named as $Err_{max}$) is proposed as a measure [19]. It is defined as

$$Err_{max} = \frac{1}{\beta N_0} \sum_{i=1}^{N_0} \left| Err'(i) \right| + \frac{1}{N_0} \sum_{i=1}^{N_0} \left| S(n) \right|^2$$ (23)

where $N_0$ is the data length, $Err'(i)$ is the sorted error values, $0 \leq \beta \leq 1$. The $Err_{max}$ is an average relative error of the maximum $\beta N_0$ error values.

For different denoising methods, the SNR enhanced ($SNR_{enh}$) can denote the global effectiveness of denoising and the maximum error ($Err_{max}$) can denote the ability to suppress outliers in heavy-tailed noise; the combination of $SNR_{enh}$ and $Err_{max}$ can measure the ability to suppress heavy-tailed noise [19].

According to $SNR_{enh}$ and $Err_{max}$ the robust threshold is compared with classical threshold in Fig. 7. The original
signal is sine wave signal, and Monte Carlo simulation is used to evaluate $SNR_{enh}$ and $Err_{max}$ of two thresholds over a range of SNR. Where 300 experiments were conducted at each value of SNR; the soft threshold is adopted for both methods; and the solid line and dotted line denote the robust threshold and the classical threshold respectively.

According to Fig. 7, from either $SNR_{enh}$ or $Err_{max}$, the robust threshold performs much better than classical threshold. When SNR>8dB, $SNR_{enh}$ of robust threshold is lower than that of classical threshold, because SNR of contaminated signal is too high and the number of outliers decreases in heavy-tailed noise. When the distribution of noise approaches Gaussian, the advantage of robust threshold over classical threshold vanishes. According to $Err_{max}$ in Fig. 7, it is proved that two error curves of different thresholds are nearly the same at SNR>4dB. In a word, the robust threshold outperforms the classical threshold in removing heavy-tailed noise, especially for low SNR.

In Fig. 8, according to $Err_{max}$, the soft threshold and hard threshold are nearly the same. However, according to $SNR_{enh}$, the soft threshold outperforms the hard threshold at SNR>5dB. When the original signal is square wave signal or triangular wave signal, the same results are obtained. It is concluded that soft threshold is more suitable than hard threshold for robust wavelet threshold technique.

### D. Discussion on Soft and Hard Threshold

During the above simulations, soft thresholding technique is adopted. In order to determine the better one for robust wavelet threshold technique between soft threshold and hard threshold, $SNR_{enh}$ and $Err_{max}$ of soft threshold and hard threshold are compared.

For robust threshold technique, the soft and hard thresholds are compared. The original signal is still sine wave signal, and Monte Carlo simulations with 300 experiments are conducted. $SNR_{enh}$ and $Err_{max}$ of soft and hard thresholds over a range of SNR are shown in Fig. 8, where the solid line and the dotted line denote soft threshold and hard threshold respectively.

E. Application in Gas Sensor Signal Denoising

Semiconductor gas sensors suffer from serious shortcomings such as poor selectivity, low repeatability and response drift. In order to overcome these disadvantages, the temperature modulation technique is proposed [21-22]. By modulating the operating temperature of gas sensors, this technique has been remarkably successful in many applications. Temperature modulation alters the kinetics of the adsorption and reaction processes that take place at the sensor surface while detecting reducing or oxidizing species in the presence of atmospheric oxygen. This leads to the development of response patterns, which are characteristic of the species being detected. In other words, by retrieving information from response dynamics, new response features are obtained that confer more selectivity to metal oxide sensors.

The extraction of features from the response of chemical sensors consists in the selection of some characteristics of their temporal response sequence, which results from the interaction between sensors and the compounds to be detected. The extracted features are then input to pattern recognition systems. From a general point of view, a chemical sensor can be considered as a dynamic system whose response signal temporally evolves following, with its proper dynamics, the analytes
and their concentration. Therefore, Wavelet analysis has been employed to study the properties of dynamic signals. Features could be extracted from the wavelet coefficients [23-24].

However, the real measured gas sensor signal suffers from the noises, especially the outlier noise. The upper subplot X in Fig. 9 shows a real test of modulated gas sensor signal. It can be seen that the noise is quite the same as heavy-tailed noises discussed above. It also obeys the heavy-tailed noise probability distribution. Before extract features, the signal should be denoised. Generally used classical threshold is adopted and the result is shown in the middle subplot of Fig. 9. For the distinct outliers, it has small effects. For comparison, the robust threshold is adopted and the result is shown in the third subplot of Fig. 9. It can be seen that the noises are almost eliminated, which shows its good performances.

V. CONCLUSION

Based on the probability model for heavy-tailed noises and the wavelet denoising method, the robust wavelet threshold is studied in detail. According to an appropriate effectiveness measure for removing heavy-tailed noise, the classical Donoho threshold method and the robust wavelet threshold method are compared by Monte Carlo simulation. Following conclusions are drawn from the simulation results as following:

(1) For the heavy-tailed noise that has more outliers than Gaussian noise, the robust threshold can suppress outliers more effectively than the classical Donoho threshold.

(2) With unknown \(\varepsilon\), the robust threshold can also detect signal in heavy-tailed noise, which shows its robustness.

(3) The soft threshold is more suitable than the hard threshold for robust wavelet threshold technique.

(4) The robust wavelet threshold approach is effective to decrease the heavy noises from gas sensor dynamic signals. It is a quite prospective approach in signal denoising area.

However, there are still some problems need to be studied further, such as how to determine the best wavelet basis function and the optimum decomposition level. They are the further problem to be solved.
